

PEGASE: A robust and efficient tool for worst case network traversal time evaluation on AFDX

Marc Boyer, ONERA

Jörn Migge, RealTime-at-Work

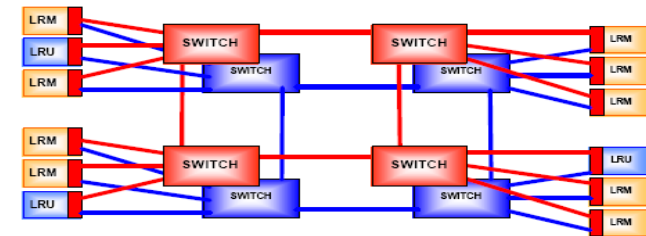

Marc Fumey, Thales Avionics

AFDX

- ▶ Avionics Systems: communicating real-time systems
- ▶ AFDX: Avionics Full Duplex ethernet
 - New avionics backbone
 - Ethernet-based
 - Full Duplex => no collision
- ▶ Shared network
 - Indeterminism at the switch level
 - Need for guaranteed bounds
(e.g. frame Worst-Case Traversal Times and buffers size)

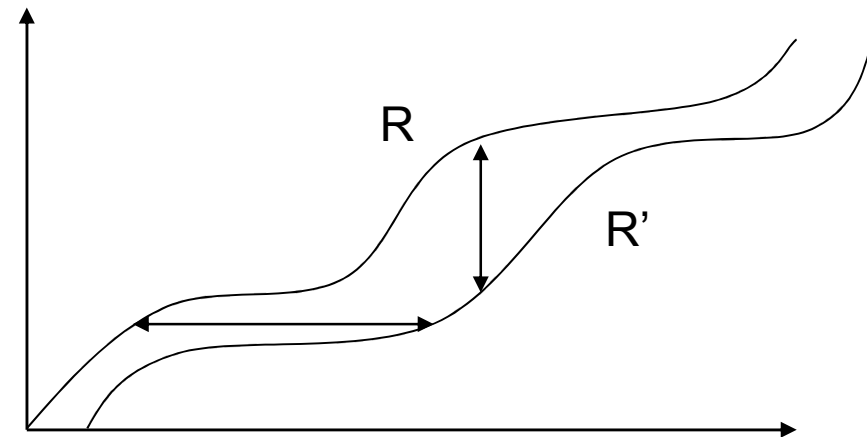

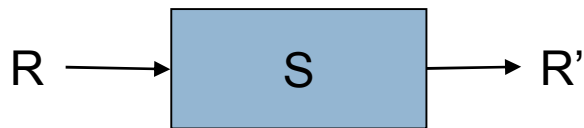

- One LRM = Several functions
- **AFDX Network**
 - 100Mbps
 - Internet protocols
 - Virtual Links
 - Determinism
 - Redundancy
 - Less Cables
 - Flexibility

SAE *International*[™]

Network Calculus

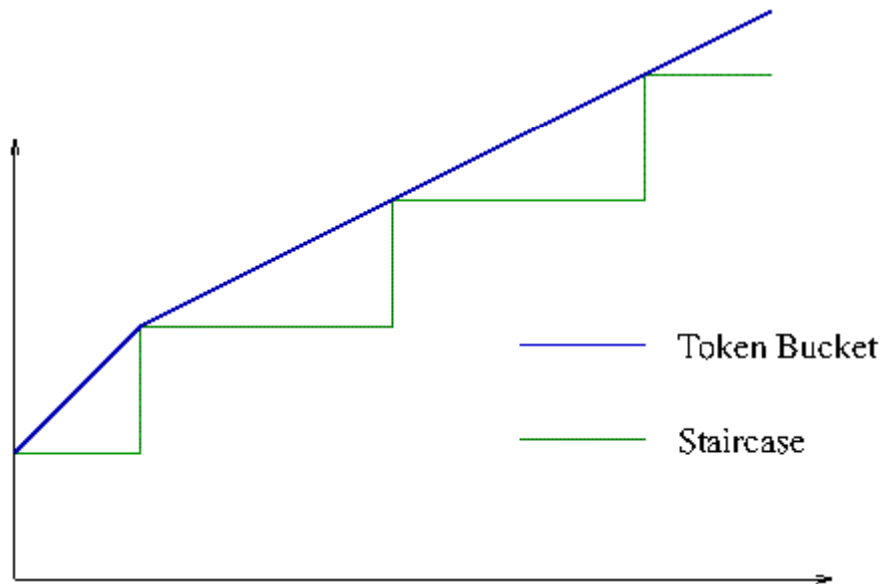

- ▶ Bound computation method: Network Calculus
- ▶ Formal Framework
 - Strong background: $(\min, +)$ algebra
 - Very general and flexible model

SAE *International*TM

Network Calculus Flexibility

- ▶ Modeling (periodic+jitter flow)
 - Simple constraint : Token bucket
 - Tight constraint : Stair Case

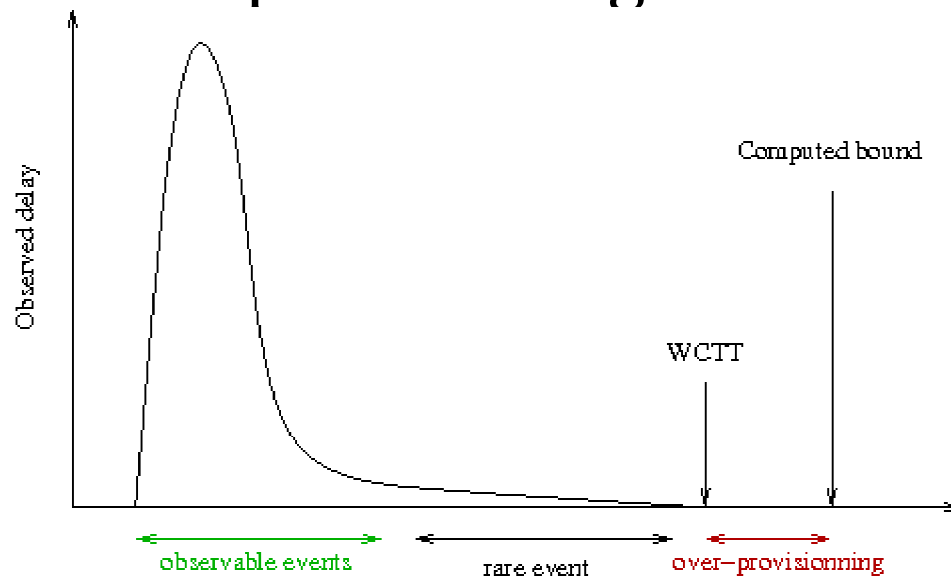

SAE *International*[™]

PAPER 2011-01-2711

Network Calculus and AFDX

- ▶ Network calculus used to certify A380 AFDX
- ▶ Network calculus bounds never reached
- ▶ Challenge: reduce over-approximation => reduce over provisioning

SAE International™

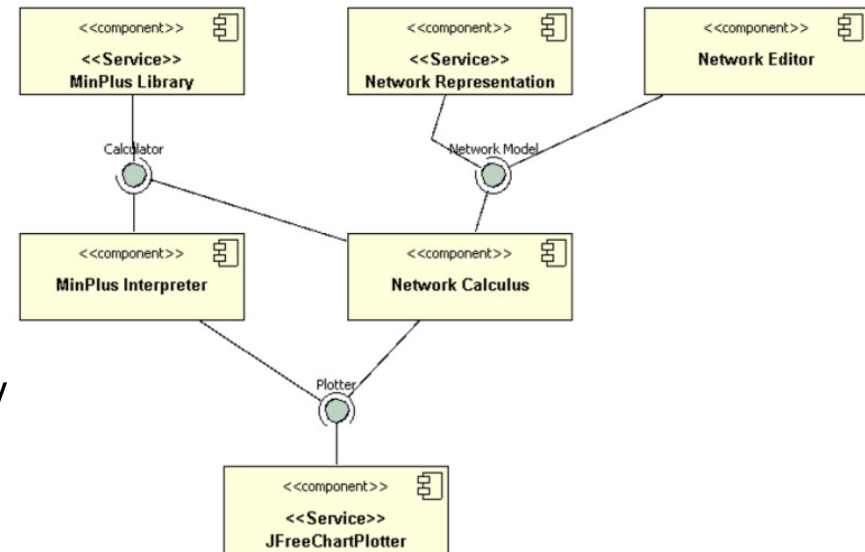

The PEGASE Tool

► Requirements :

- Accurate results (up to date wrt Network Calculus theory)
- Extendable (to support exploratory works)
- Trustable
- Domain-specific editor
 - (creating networks without being network calculus specialist)
- Containing computation time
- Conflicting requirements
 - ⇒ Modular conception

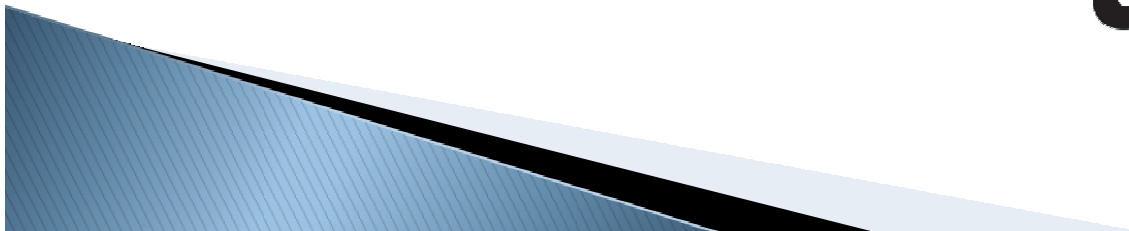

PEGASE Modular Architecture

- ▶ Decomposed into components
- ▶ Some components has several implementations (tradeoff complexity / accuracy / simplicity)
- ▶ Different users – different components

Modular Conception example

- ▶ Floating point vs Rational Numbers
 - Floating point (2.0, 0.666) : Fast, but rounding errors
 - Rational numbers (2, 2/3): Exact, but slow
- ▶ Function classes
 - ICC: Increasing Convex and Concave (Piecewise Linear)
 - 1292 LOC / Rational and floating point Version
 - Coarse modeling: token-bucket constraint
 - UPP: Very general class of Piecewise linear function
 - 3416 LOC / Rational only
 - Tight modeling: sporadic messages

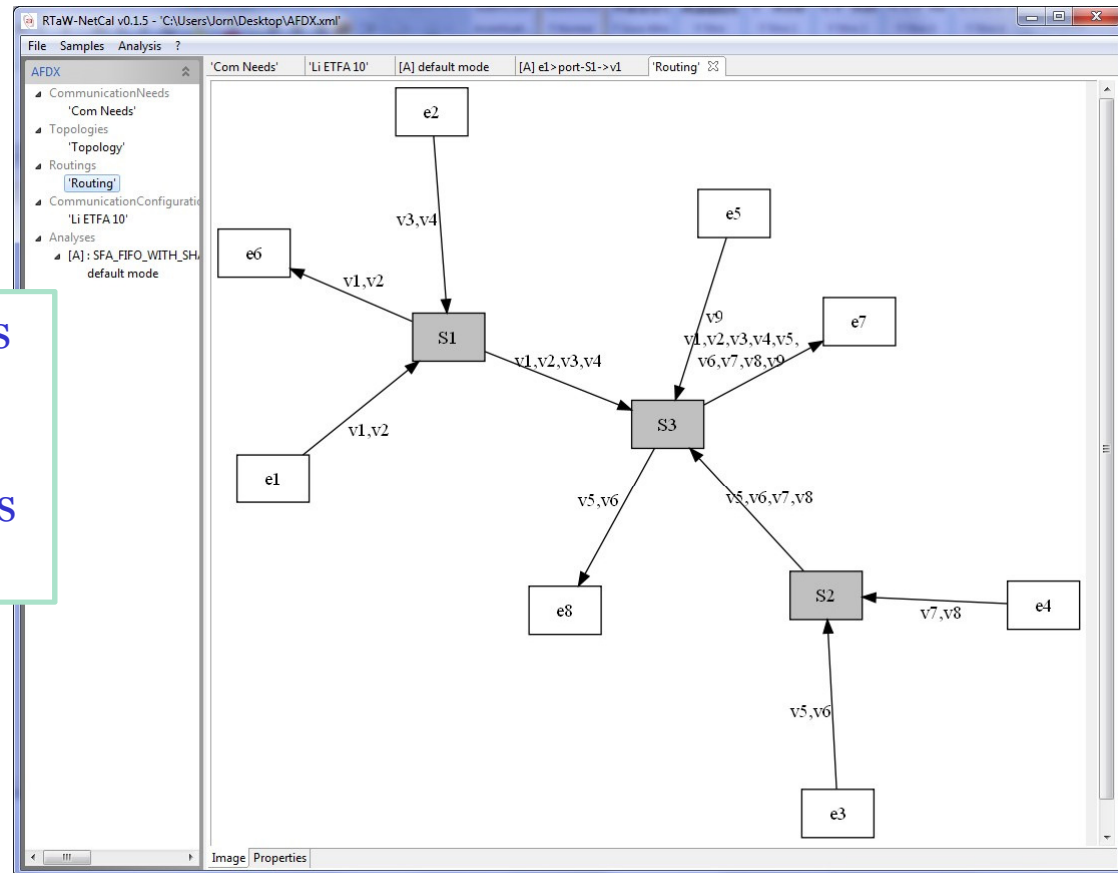

Different modules / different complexities

Module	#Lines of code	Complexity (Cyclomatic)	#Methods	Cplx / #Methods
Fractions	862	268	73	3.67
Double	84	32	24	1.33
ICC	1292	318	74	4.3
UPP	3416	719	106	6.8

The network editor

The gray boxes are the switches while the end-systems are the white boxes. The names of the virtual links are shown as labels of the physical links.

Data Flows

Data Flow	P...	BAG	Max Frame Size	Sender	Receiver	Constraint	Bound
v1	1	8 ms	500 byte	e1			
				e1	e6	120 μ s	116 μ s
				e1	e7	860 μ s	872 μ s
v2	1	4 ms	750 byte	e1			
				e1	e6	120 μ s	116 μ s
				e1	e7	900 μ s	872 μ s
v3	0	2 ms	500 byte	e2			
				e2	e7	700 μ s	472 μ s
				e2	e7	900 μ s	872 μ s
v4	1	16 ms	1000 byte	e2			
				e2	e7	900 μ s	872 μ s
				e2	e7	900 μ s	892 μ s
v7	0	32 ms	1000 byte	e3			
				e3	e8	300 μ s	412 μ s
				e4	e7	1000 μ s	532 μ s
v8	1	16 ms	750 byte	e4			
				e4	e7	600 μ s	532 μ s

Red means that the time constraint cannot be guaranteed for a given virtual link.

PAPER 2011-01-2711

Illustration on realistic AFDX system

- ▶ 104 End-Systems
- ▶ 8 Routers
- ▶ 4 Priority levels
- ▶ 974 Data flows (Virtual links)
- ▶ 6501 Latency constraints
- ▶ Periods (min: 2ms / max : 128 ms / av : 60 ms)
- ▶ Path Lengths (min : 1 / max : 3 / av : 1.3)
- ▶ Constraints (min : 1ms / max : 30 ms / av: 10ms)

Computation times for different trade-offs accuracy / computing times

Configuration ID	Constraint Model	Number Type	Function Class	Computation duration
#1	Token Bucket	Float	ICC	2 s
#2	Token Bucket	Rational number	ICC	11 s
#3	Token Bucket	Rational number	UPP	19 s
#4	Stair-case	Rational number	UPP	33 mn

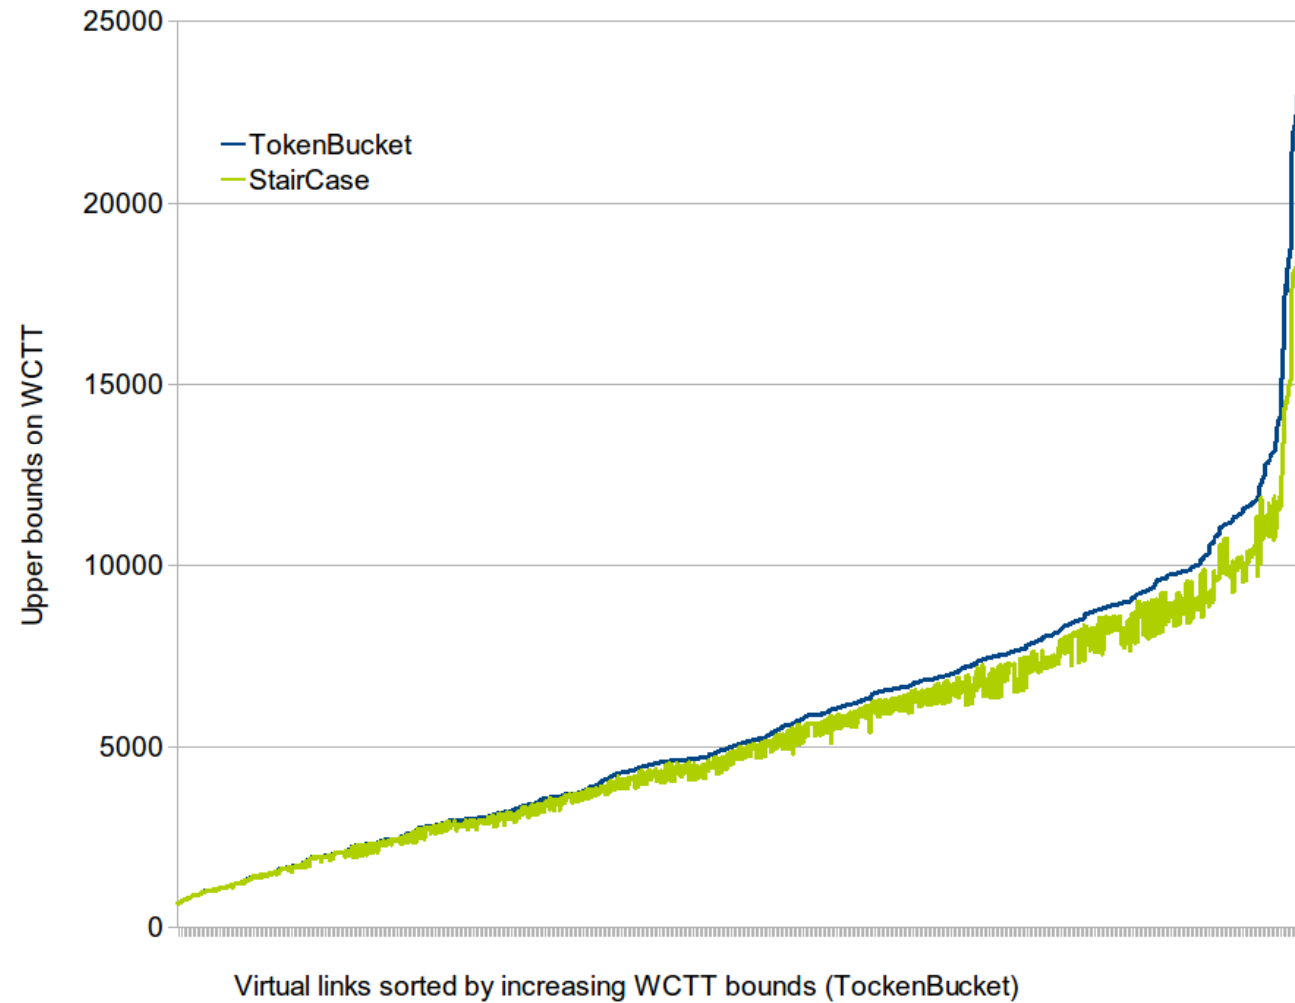

SAE *International*

WCTT Bounds Results

Warning: actual worst case traversal times (WCTT)
is unknown

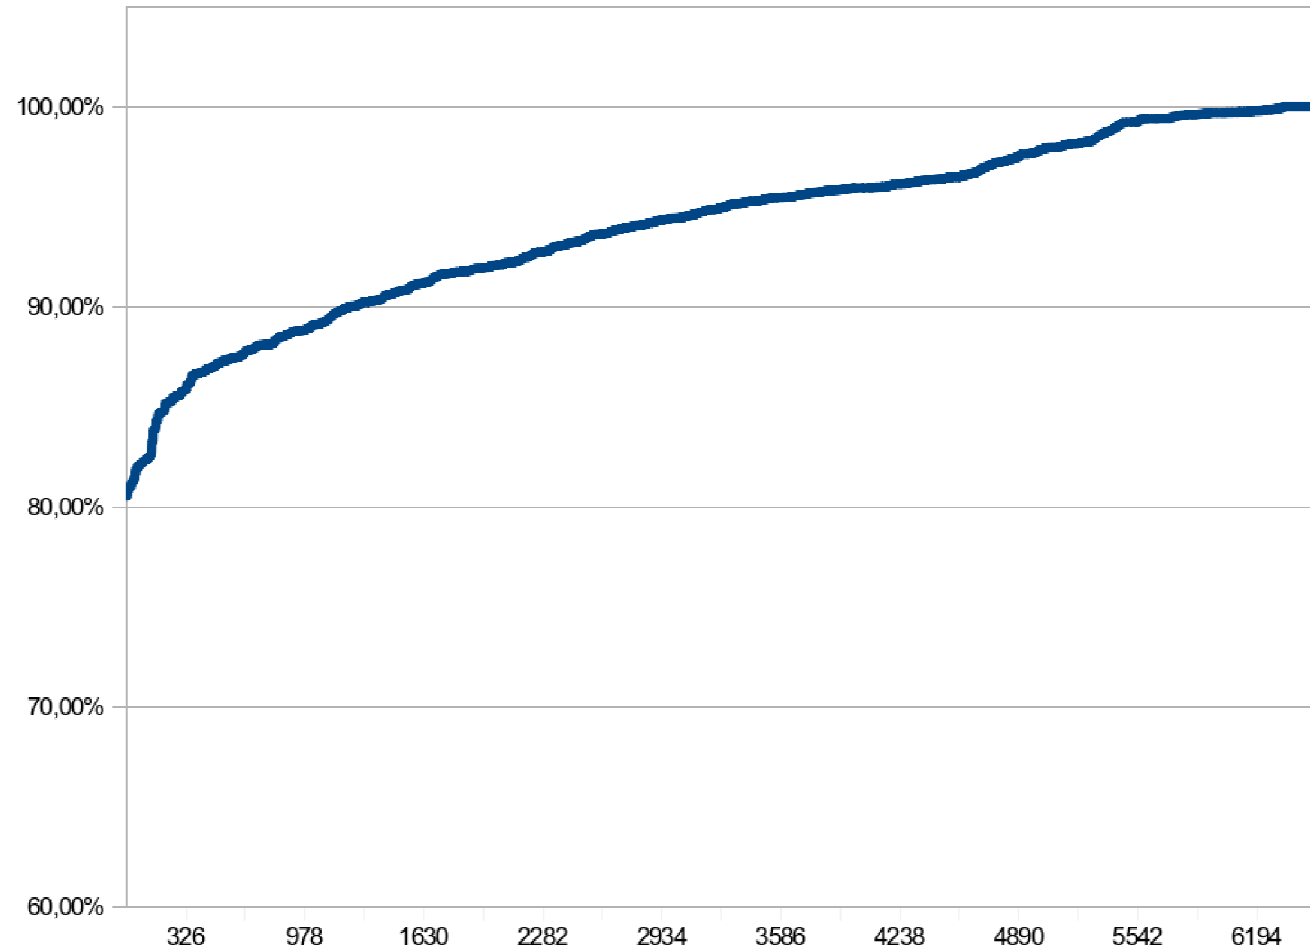

- ▶ From [Bauer 2010] :
average (WCTT – token bucket) < 13%
- ▶ Average gain Stair Case vs Token Bucket: 6%

WCTT Bounds Results for token bucket and stair-case models of the input traffic

Gain with stair-case is larger for low-priority Virtual links

Stair Case vs Token Bucket improvement (normalised)

Synthetic results

- ▶ By priority
 - High priority : no gain (0.38%)
 - Low priority: significant gains (12.5%)
- ▶ By path length (number of hops)
 - Short path: 5.7%
 - Long path (length 3): 7.3%

Conclusion

- ▶ Network calculus is a theory that is:
 - Exciting (for academics)
 - Trustable (strong formal background)
 - Flexible

- ▶ with an industrial tool : PEGASE
 - Conceived for network designers with a domain specific editor
 - Customizable performances: accuracy vs computation time
 - Enable to reduce HW resources over-provisioning
 - Increase possibility of system evolution and system re-use
